QSAR: Definition

Structure-Activity Relationship (SAR) is an approach to find qualitative relationships between chemical structure and their biological activity

Quantitative Structure Activity Relationship (QSAR) models are theoretical models that relate a quantitative measure of chemical structure to a physical property, or a biological activity

Principle: Structurally similar chemicals are likely to have similar physicochemical and biological properties

QSAR models are of the form:

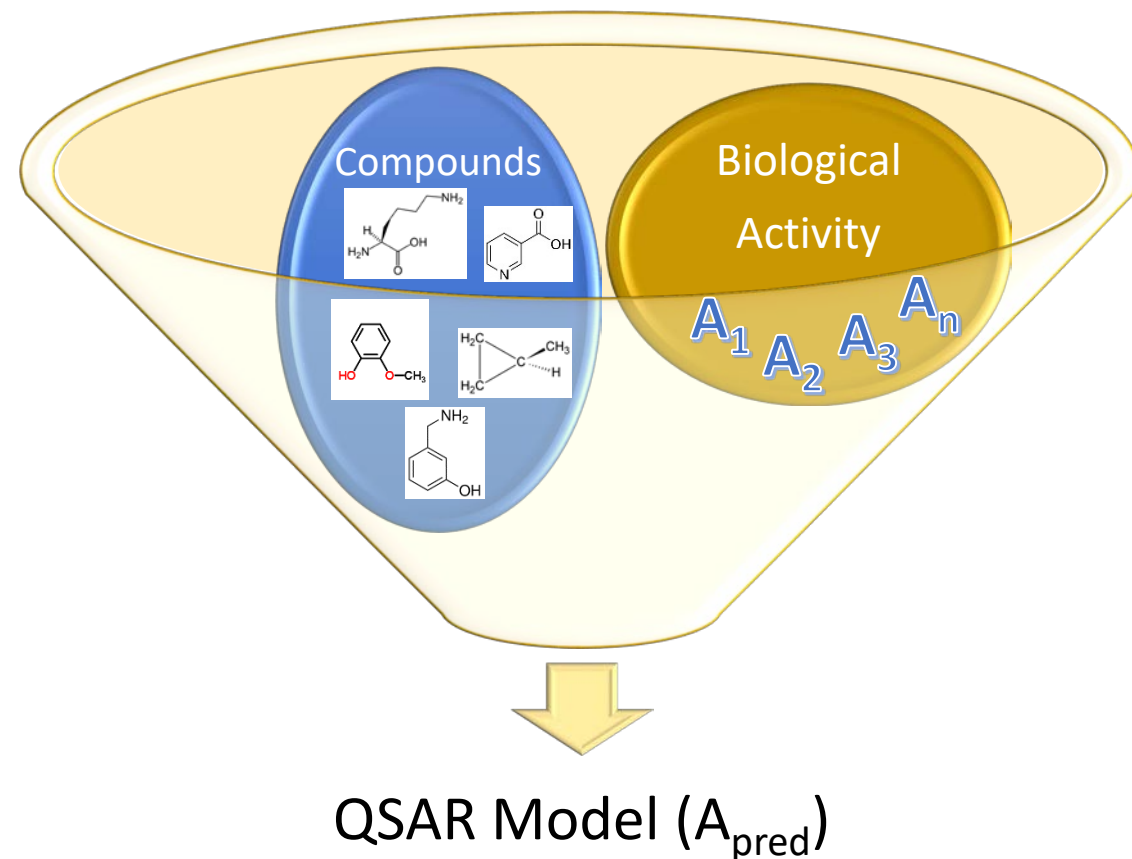

$$A_{\text{pred}} = f(D_1, D_2, \dots, D_n)$$

where,

A_{pred} : biological activity (or toxicological endpoint)

D_1, D_2, \dots, D_n : chemical or structural properties (molecular descriptors)

A_1, A_2, \dots, A_n : biological activity of training chemicals

QSAR: Tools

A number of free and proprietary (Q)SAR tools are available that can predict the toxicity of a given chemical based on its chemical structure

| | QSAR TOOLS | | |

QSARs: Needs and Applications

Too many chemicals problem

- Many chemicals to evaluate for multiple toxicity endpoints
- More sensitive analytical chemistry methods for chemical identification
- Lack of sufficient and relevant in vivo data

Alternative to animal testing

- Broad applications as a faster and cheaper alternative to animal testing methods in academia, industry and government institutions

Regulatory uses

- Supplement experimental data
- Support prioritization in the absence of experimental data
- Substitute or replace experimental animal testing methods

Rational chemical design

- Design and development of new drugs, perfumes, dye etc. in an efficient manner

Promoting green chemistry

- Design of chemical products and processes that reduce or eliminate the use/generation of hazardous substances.

QSAR: Regulatory Applicability

| | Organization | Guidelines |
|----------------|---|--|
| Multi-National | Consortium of 34 countries OECD - Organisation for Economic Co-operation and Development (Established 1961) | OECD Principles for the Validation of (Q)SARs (2004)¹ <ul style="list-style-type: none"> • A defined endpoint • An unambiguous algorithm • A defined domain of applicability • Appropriate measures of goodness-of-fit, robustness and predictivity • A mechanistic interpretation, if possible |
| European Union | Driven by the requirements for safety assessment and characterization of existing and new chemicals, the European Chemicals Agency (ECHA) established the REACH (Registration, Evaluation, Authorization and Restriction of Chemicals) regulation (Came into force 2007) <ul style="list-style-type: none"> • Animal testing is only allowed as a last resort | (Q)SARs in REACH (described in Annex XI of the REACH regulation)² <ul style="list-style-type: none"> • Results are derived from a (Q)SAR model which is scientifically valid • The chemical of interest falls under the applicability domain of the (Q)SAR model • The predictions are adequate for the purpose of classification & labeling and/or risk assessment • Adequate and reliable documentation on the (Q)SAR model and its prediction is available (structured using the OECD principles) |

QSAR WORKFLOW: Molecular Descriptors

1. Generation of molecular descriptors from chemical structure

Molecular descriptors are a quantification of the various molecular properties of a chemical compound. There are different levels of chemical representation ranging from 1D to 4D¹

Tools to calculate molecular descriptors:

| Descriptor Types | Description |
|------------------|---|
| 1D | They consider properties inferred only the chemical formula of a chemical |
| 2D | They consider properties inferred about the structure of the chemical based on the 2 dimensional structural formula |
| 3D | They consider properties inferred from the spatial shape of the chemical for one conformation |
| 4D | They are similar to 3D descriptors extended to multiple conformations |

| Descriptor Name | Descriptor Type | Availability |

QSAR WORKFLOW: Molecular Descriptors

1. Generation of molecular descriptors from chemical structure

2D descriptors are the most commonly used molecular descriptors

| 2D Descriptor Types | Description | Examples |
|----------------------------|--|---|
| Constitutional Descriptors | They represent properties related to molecular structure | molecular weight, total number of atoms in the molecule, number of aromatic rings |
| Electrostatic | They represent properties related to the electronic nature of the compound | atomic net and partial charges |
| Topological Descriptors | They represent properties which can be inferred by treating the structure of the compound as a graph, with atoms as vertices and covalent bonds as edges | total number of bonds in shortest paths between all pairs of non-hydrogen atoms |
| Geometrical Descriptors | They represent properties related to spatial arrangement of atoms constituting the compound | Vander Waals Area |
| Fragment based Descriptors | They represent properties related to sub-structural motifs | MDL Keys and Molecular Fingerprints |

QSAR WORKFLOW: Feature Selection

2. Selection of
most relevant
molecular
descriptors

Improves Interpretation

- Less features, simpler models.
- Expert-driven feature selection enhances the mechanistic interpretation of the models.

Reduces Overfitting

- Less redundant data means lesser decisions based on noise.

Reduces Training Time

- Less data to learn from ensures quicker model development.

QSAR WORKFLOW: Model Development

3. Statistical mapping of the descriptors to a toxic endpoint

k-nearest Neighbor is a non-parametric method used in classification and regression problems.

Principle: The property of an instance (chemical) is similar to instances close to them, where closeness is defined by the appropriate *distance function* using the feature space (molecular descriptors).

Highlights

- Different distance functions available: Euclidean, Manhattan, Minkowski
- Simple to implement
- Easy to interpret (conceptually similar to read-across)

QSAR WORKFLOW: Model Development

3. Statistical mapping of the descriptors to a toxic endpoint

Support vector machine is a linear binary classifier which calculates an optimal hyper-plane for categorizing data.

The hyper-plane separates all data points of one class from those of the other class and is used to classify any new data points

Highlights

- Different kernel methods available for linear and non-linear data separation
- Especially suited for problems with small sized training data and binary classifiers

QSAR WORKFLOW: Model Development

3. Statistical mapping of the descriptors to a toxic endpoint

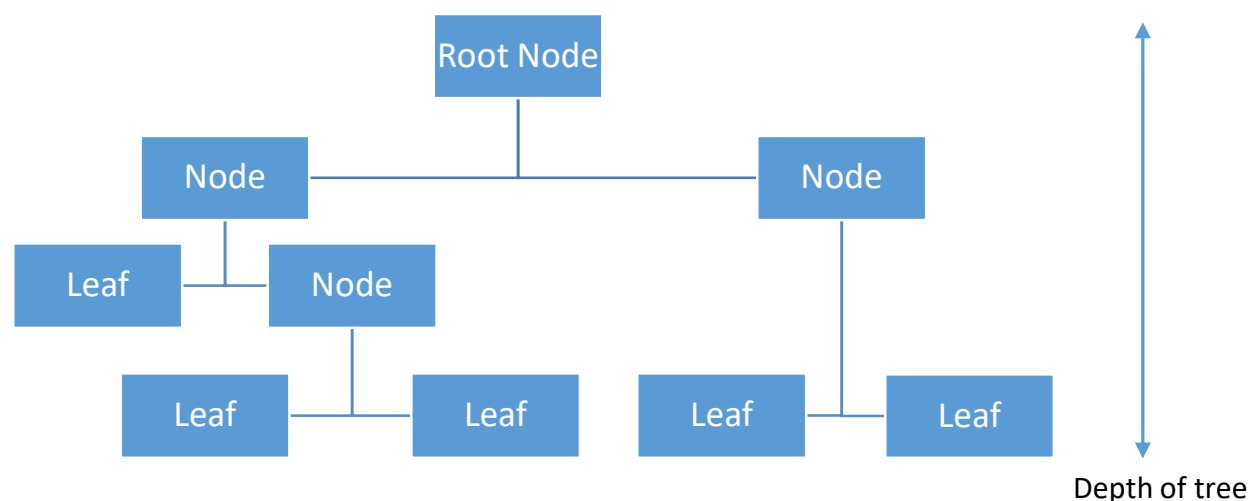

Decision tree is a non-parametric supervised learning method used for classification and regression. It is a divide and conquer algorithm that works by partitioning the data into subsets that contain data with similar values

Decision Tree Components

- **Root node** is the starting point of the tree
- **Node** is the decision point from where data is partitioned into subsets
- **Branches** are the decision outcome path that lead to a node/leaf
- **Leaf node** is the last stage of the decision path when an outcome is reached

Image:
<http://grannysuesnews.blogspot.com/2011/05/tree-of-hearts.html>

Decision Tree Hyper-parameters

- Depth of tree
- Minimum number of samples to split at a node
- Maximum number of features to consider at each split

Decision Tree Limitations:

- Overfitting
- Underfitting
- High variance

QSAR WORKFLOW: Model Development

3. Statistical mapping of the descriptors to a toxic endpoint

Random forest constructs an ensemble of random decision trees. The new data is classified based on the majority prediction of all the trees in the ensemble.

Principle

High variance can be mitigated by averaging predictions from multiple decision trees.

Method: Each tree is developed by

- Selecting a bootstrap sample from the training data with replacement,
- Randomly selecting the best descriptor variables at each node and growing the tree, and then
- Estimating the classification error by testing the tree on the remaining data.

The new data is classified based on the majority prediction of all the trees in the ensemble

Highlights

- Intrinsic feature selection
- Cross-validation not necessary
- 2 key hyper-parameters need tuning

QSAR: Workflow

```
graph LR; A[1. Generation of molecular descriptors from chemical structure] --> B[2. Selection of most relevant molecular descriptors]; B --> C[3. Statistical mapping of the descriptors to a toxic endpoint]; C --> D[4. Model validation]; D --> E[5. Model application]; D --> F[6. Documentation]; E --> F;
```

1. Generation of molecular descriptors from chemical structure

2. Selection of most relevant molecular descriptors

3. Statistical mapping of the descriptors to a toxic endpoint

4. Model validation

5. Model application

6. Documentation

1. Internal validation [x%]
 - K-fold cross validation: The dataset is split into K parts. K models are developed using (K-1) sets and the Kth set is used as the test set.
 - Leave one out cross-validation: N models are developed each with (N – 1) chemicals as training set and 1 chemical as the test set.
2. External test set validation [(100- x)%]

Classification Model Metrics

- Accuracy
- Sensitivity
- Specificity
- Balance Accuracy
- Positive Predictivity
- Negative Predictivity
- Receiver operating curves

Regression Model Metrics

- Root-mean-squared-error
- Mean Average Error
- Coefficient of Determination

QSAR: Workflow

```
graph LR; A[1. Generation of molecular descriptors from chemical structure] --> B[2. Selection of most relevant molecular descriptors]; B --> C[3. Statistical mapping of the descriptors to a toxic endpoint]; C --> D[4. Model validation]; D --> E[5. Model application]; D --> F[6. Documentation]; E --> F;
```

1. Generation of molecular descriptors from chemical structure

2. Selection of most relevant molecular descriptors

3. Statistical mapping of the descriptors to a toxic endpoint

4. Model validation

5. Model application

6. Documentation

The applicability domain (AD) of a QSAR model is defined as the "the response and chemical structure space in which the model makes predictions with a given reliability".¹

AD evaluation enables the assessment whether the model will be useful and applicable to new chemicals.

QSAR: Limitations and Challenges

1. Lack of proper chemical coverage in the training datasets which affects the applicability domain of the models and subsequently their suitability across different chemical classes
2. Low predictivity for mechanistically complex endpoints
3. Effect of quality and quantity of underlying training data

Image: Mansouri et al. "CERAPP: Collaborative Estrogen Receptor Activity Prediction Project"

[1] P. Pradeep. Hybrid Computational Toxicology Models for Regulatory Risk Assessment

[2] Pradeep et al. An ensemble model of QSAR tools for regulatory risk assessment. J. Cheminform., 8 (2016), p. 48.

QSAR: Limitations and Challenges (Contd.)

- Conflicting predictions raise interpretation, validation and adequacy concerns
- Optimization of false positives and false negatives is important. E.g.,
 - A chemical that is falsely predicted non-carcinogenic may pass regulatory approval but will cause exposure risk to cancer
 - A drug that is known to cure depression can be approved if it causes skin sensitization but not if it induces tumors
- Choice of an appropriate tool for evaluation of toxic effects in the absence of experimental data is difficult. E.g.
 - January 2014 Elk River 4-methylcyclohexanemethanol (MCHM) spill, West Virginia

Nano-QSAR or QNAR: Challenges

The recent status and proof-of-concept studies demonstrate that QSAR modeling technique can be extended to successfully predict the biological effects of nanoparticles.

Challenges

- Lack of systematic studies for the determination of physicochemical properties of nanoparticles
- Limited strategies for the characterization (molecular descriptors) of nanomaterials unlike chemicals
- Lack of experimental data for training the models
- Limited understanding on the mechanisms of interactions between nanoparticles and biological systems
