

A Case Study: Using New Approach Methods to Assess Estrogen Receptor Activity

Richard Judson, EPA Center for Computational Toxicology and Exposure

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY

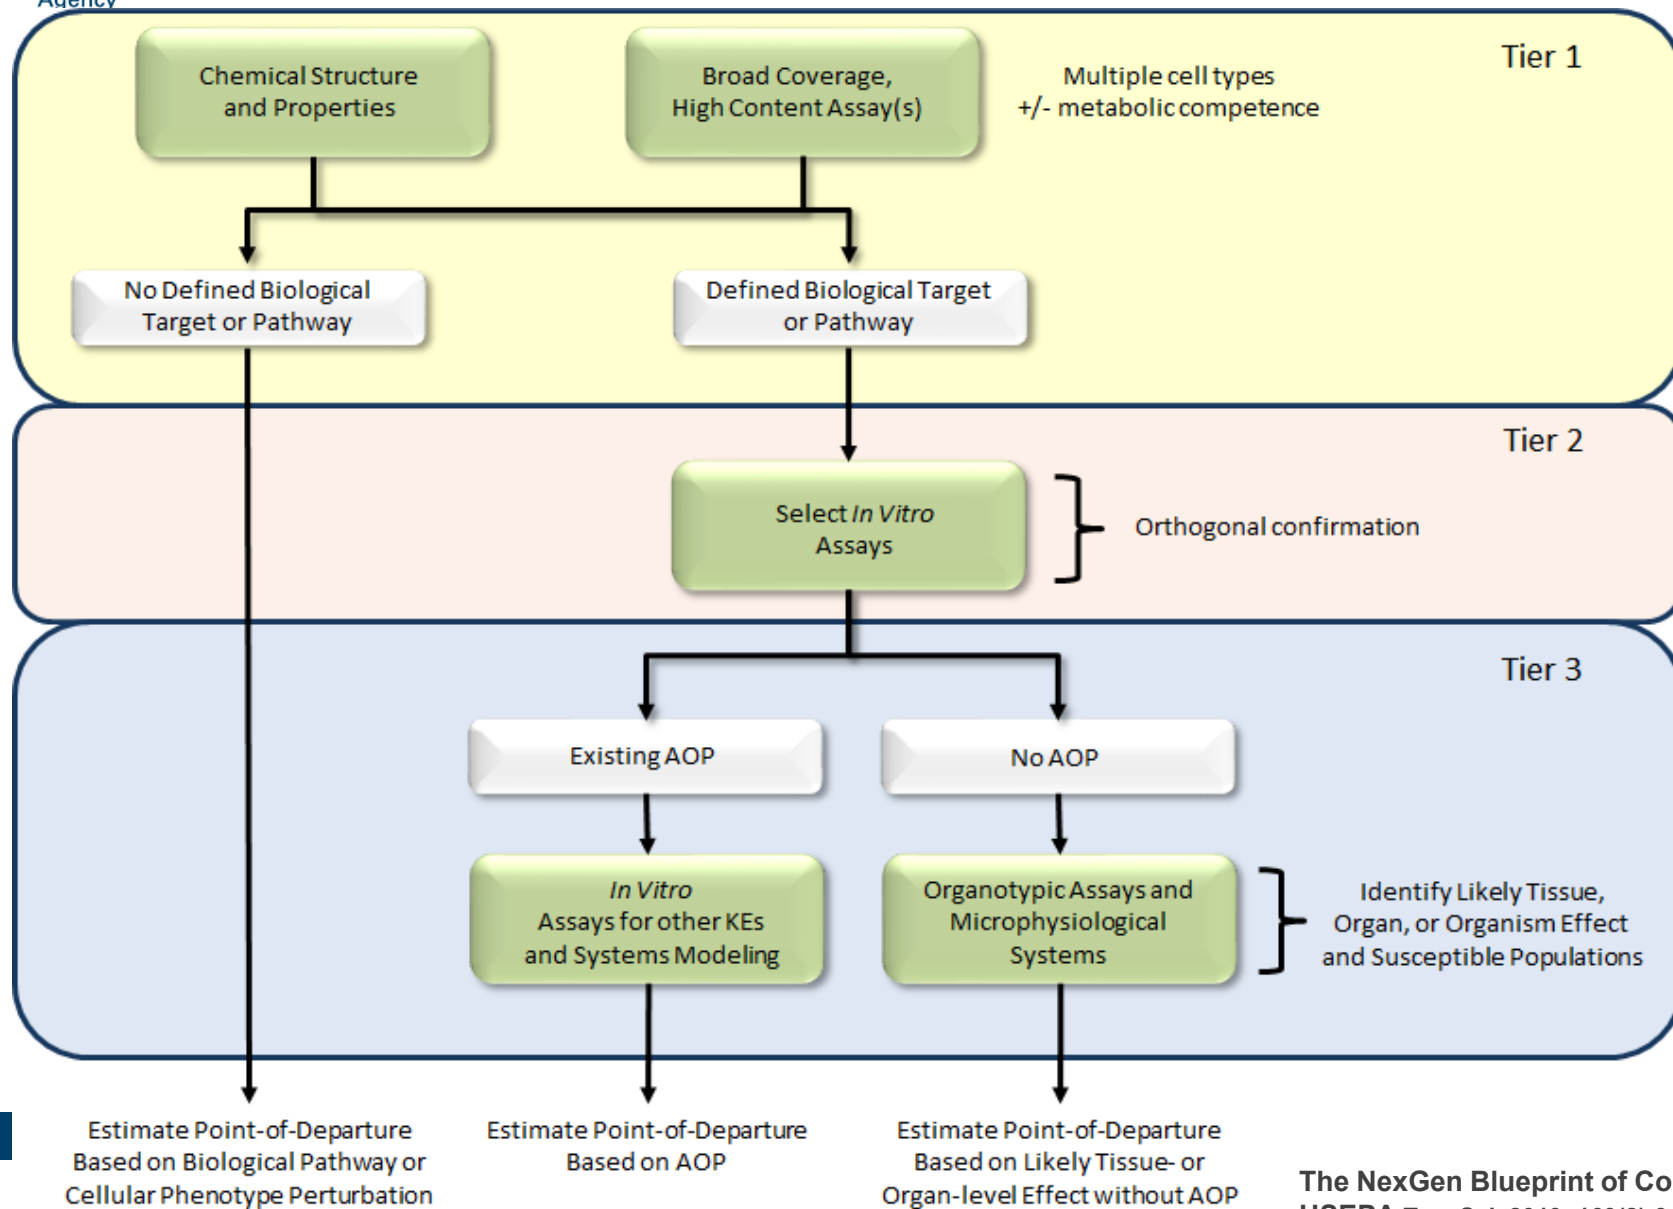

Toxicology Track: Integrated Approaches
Summer School 2020: Innovative Science Without Animals
June 22 – 26, 2020

Big Questions

1. At what dose does a chemical cause adverse affects?
2. What effects does the chemical cause?
3. Can we answer 1 and 2 without using animals?

NAMs (New Approach Methodologies) attempt to answer these

Tiered Hazard Evaluation Approach

New Approach Methods

- In silico (e.g. QSAR and Read-across)
 - Estimate effects and doses
- In vitro assays
 - Broad / screening (transcriptomics, cell painting)
 - Targeted (receptors, enzymes)
 - In vitro PODs, modes / mechanisms of action
- In vitro Toxicokinetics
 - Allow conversion of an in vitro POD to in vivo (IVIVE)
- Computer models
 - Integrate multiple in silico and in vitro data streams
- Databases of existing traditional toxicology data
 - Enables training and validation of NMA models

Illustrating NAMs

OECD Staging:

1. IATA (Integrated Approach to Testing and Assessment)
2. DA (Defined Approach)
3. TG (Test Guideline)

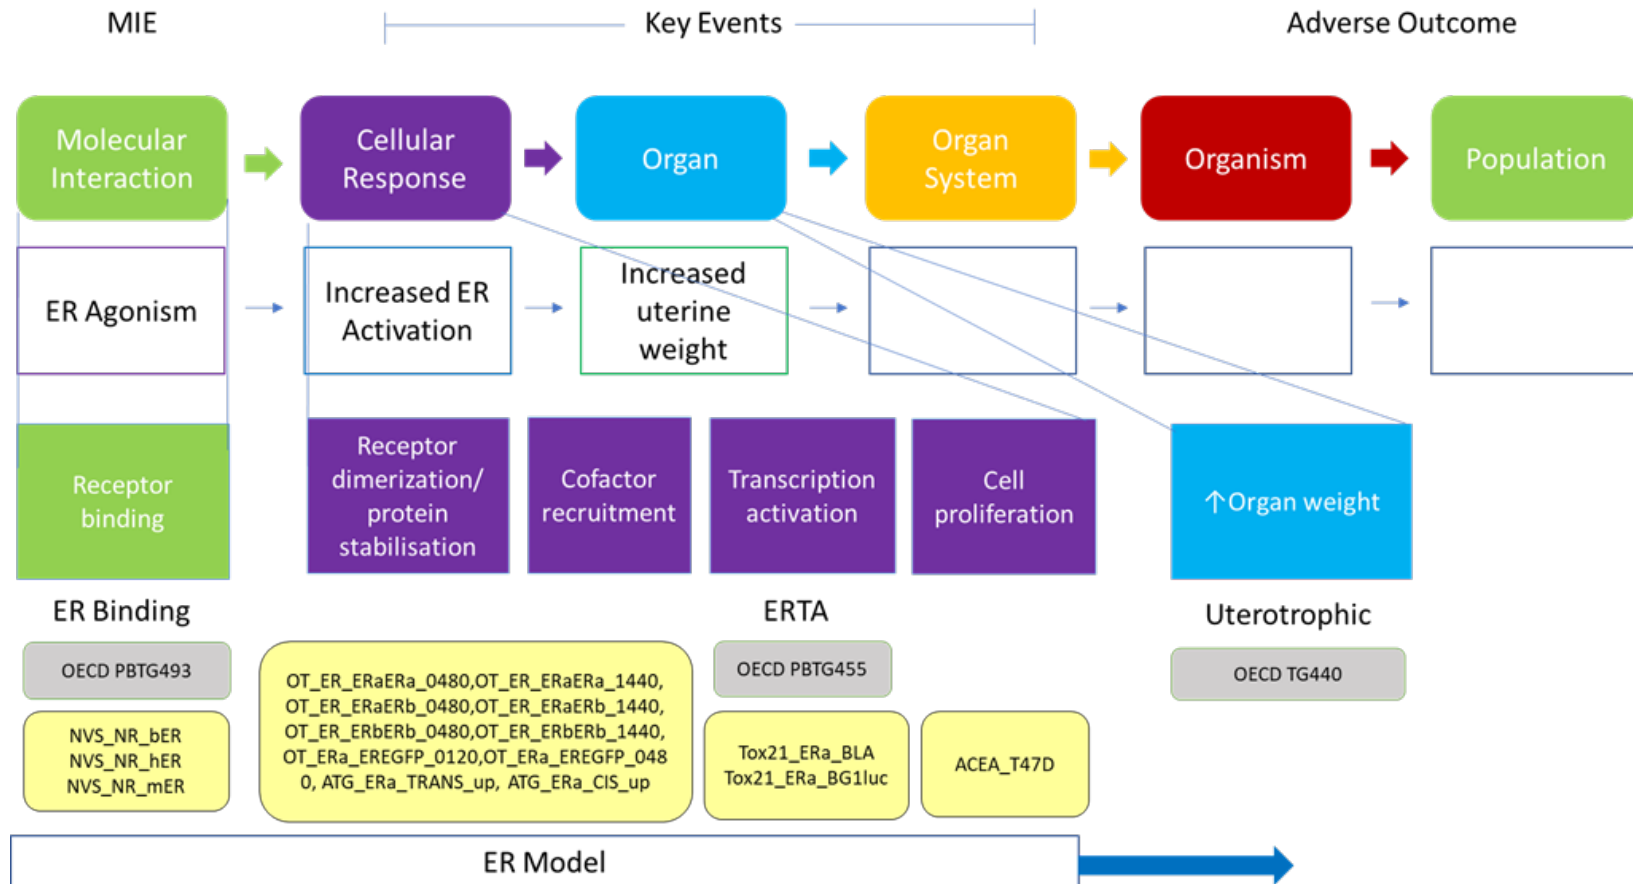

US EPA may accept tests / approaches / models without OECD acceptance

Use example of Estrogen Receptor (ER) activity

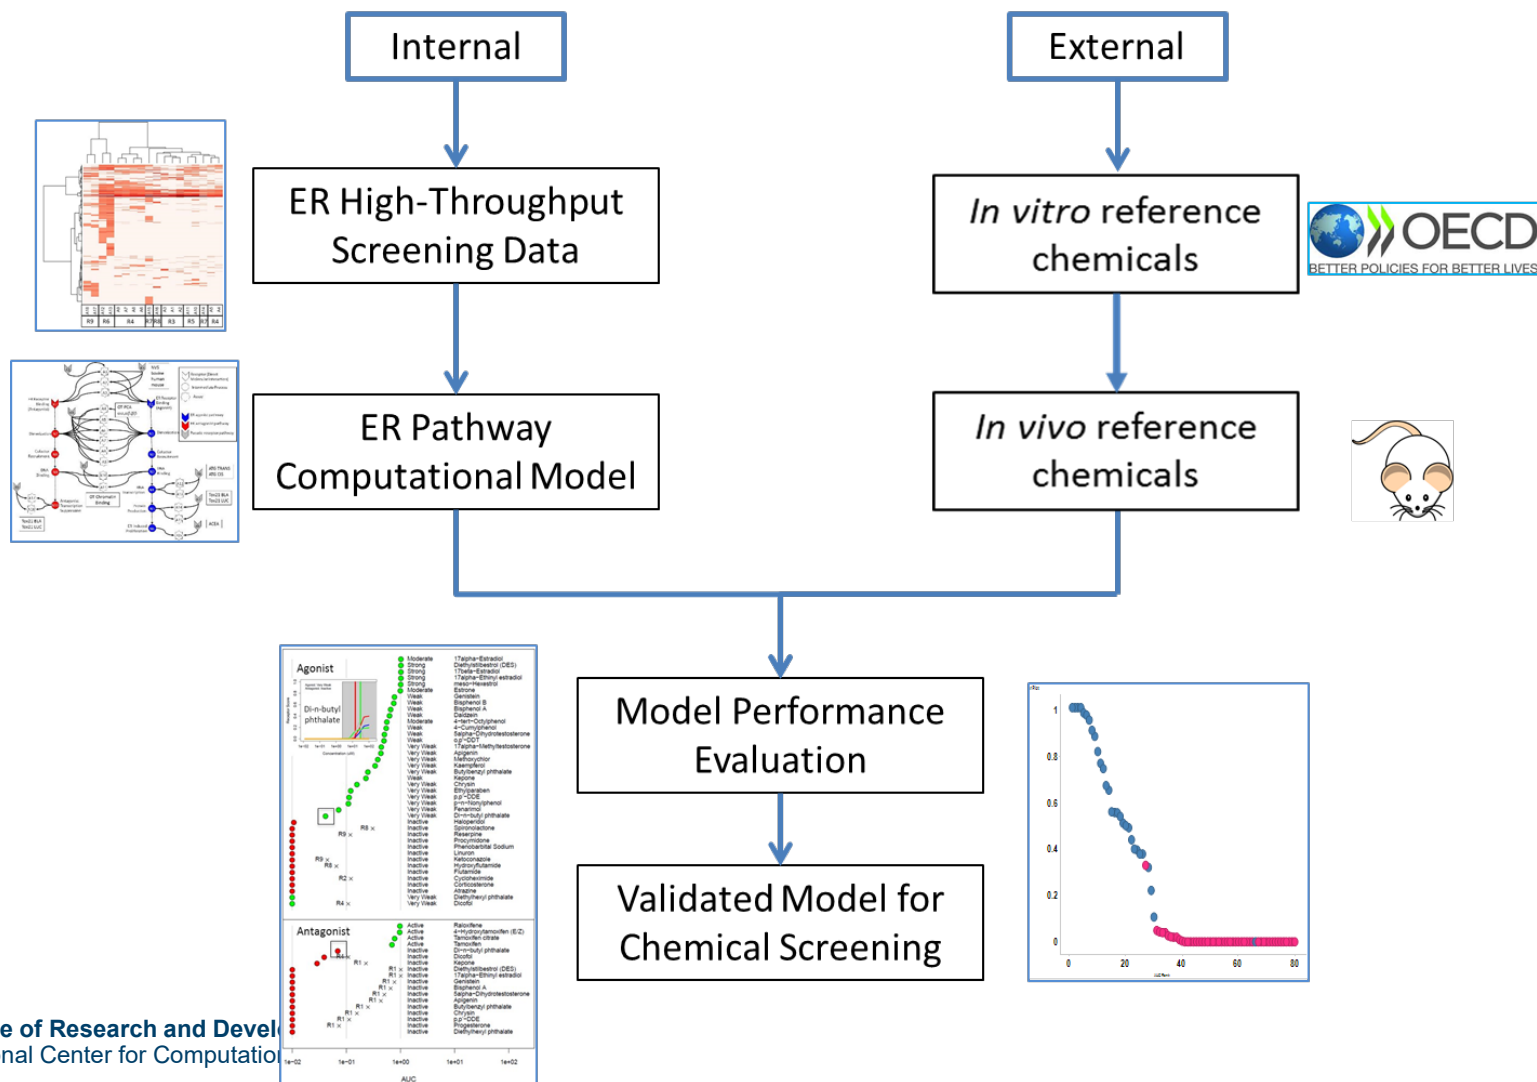

EDC Context

- Endocrine disrupting chemicals are a diverse set of substances that have the potential to interfere with normal endocrine function and lead to an adverse outcome.
- Regulatory agencies in many countries evaluate endocrine activity of environmental chemicals for specific regulatory endpoints.
- The integrated approach to testing and assessment (IATA) describes an integrated testing strategy (ITS) for the identification of endocrine disruption via estrogen receptor agonism by a substance.
- Screen chemicals for possible further testing

Linking *in vitro* to *in vivo* biology using an Adverse Outcome Pathways (AOP)

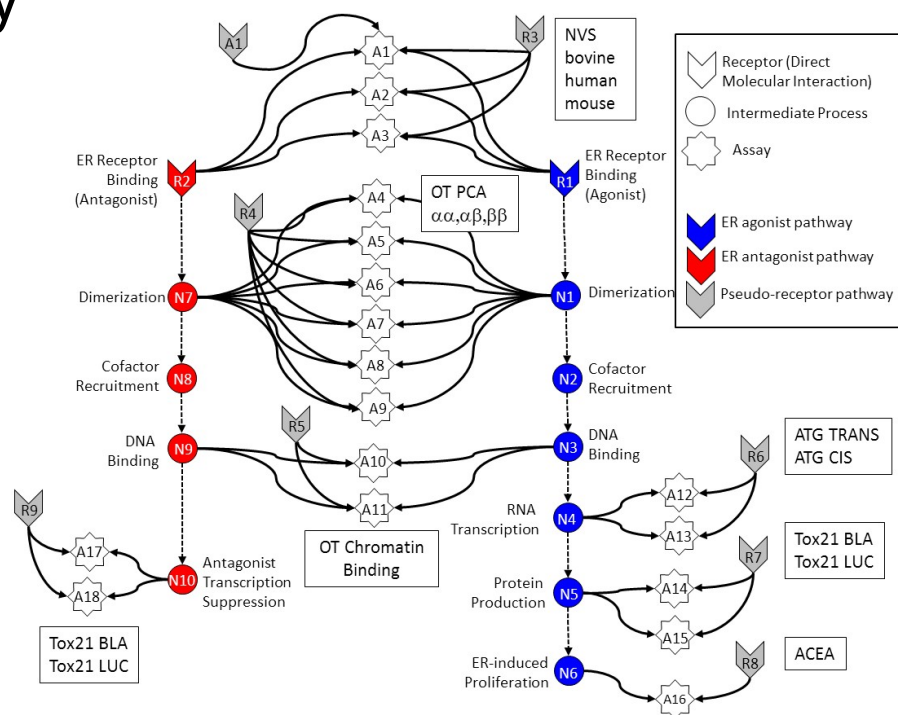

IATA Overall Approach

In Vitro Estrogen Receptor Model

- Use multiple assays per pathway
 - Different technologies
 - Different points in pathway
- No assay is perfect
 - Assay Interference
 - Noise
- Use model to integrate assays
- Evaluate model against reference chemicals

What Does the Model Do?

- For every concentration, look at the pattern of activity across the assays
 - If pattern is consistent with agonist activity, classify the chemical as an agonist
 - If pattern is consistent with antagonist activity, classify the chemical as an antagonist
 - Else, classify the chemical as acting through some technology or cell-type specific interference process

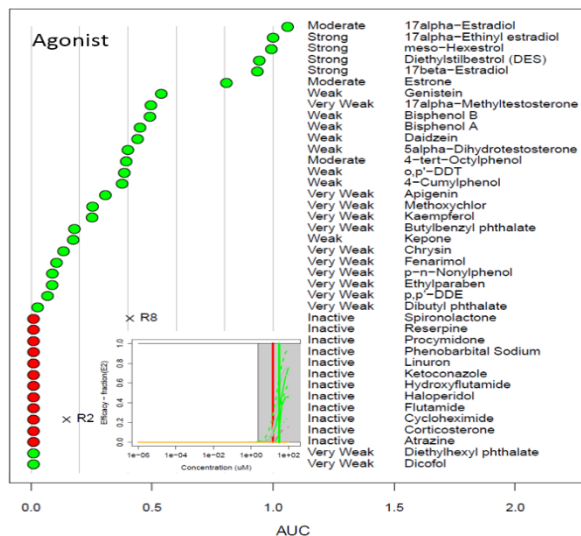

Demonstrate that the full model replicates reference chemical activity

True Positive	26 (25)
True Negative	11 (11)
False Positive	1 (0)
False Negative	2 (2)
Accuracy	0.93 (0.95)
Sensitivity	0.93 (0.93)
Specificity	0.92 (1.0)

In Vitro

True Positive	29
True Negative	46
False Positive	1
False Negative	1
Accuracy	0.97
Sensitivity	0.97
Specificity	0.97

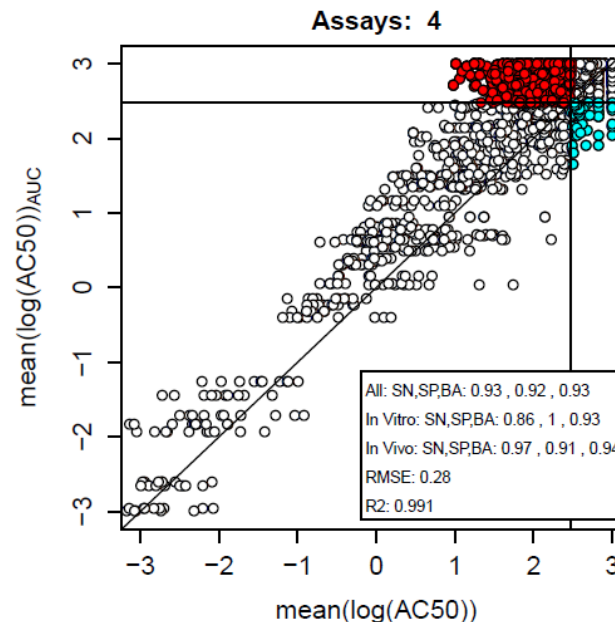

In Vivo

Moving to a Practical Application

- Full model requires ...
 - 16 assays in agonist mode, many not commercially available
 - A complex mathematical model
 - But serves as benchmark (not the “truth”) for evaluating simpler models
- “Subset models” perform almost as well
 - Use a subset of as few as 4 assays (one can be a QSAR model)
 - Combining rule uses simple arithmetic (average potency across assays)
- The IATA and DA (defined approach) are built around these simple subset models

Demonstrating the performance of the simple model

- Show that simple arithmetic can reproduce the mathematical model within the uncertainty of the model
 - Does not need to be perfect because current tests are variable
- Show that subsets (including QSAR model) are still accurate within the uncertainty of the model
- In both cases, chemicals that are misclassified are mostly “inactive” or “very weak”, and are ones that current tests may misclassify

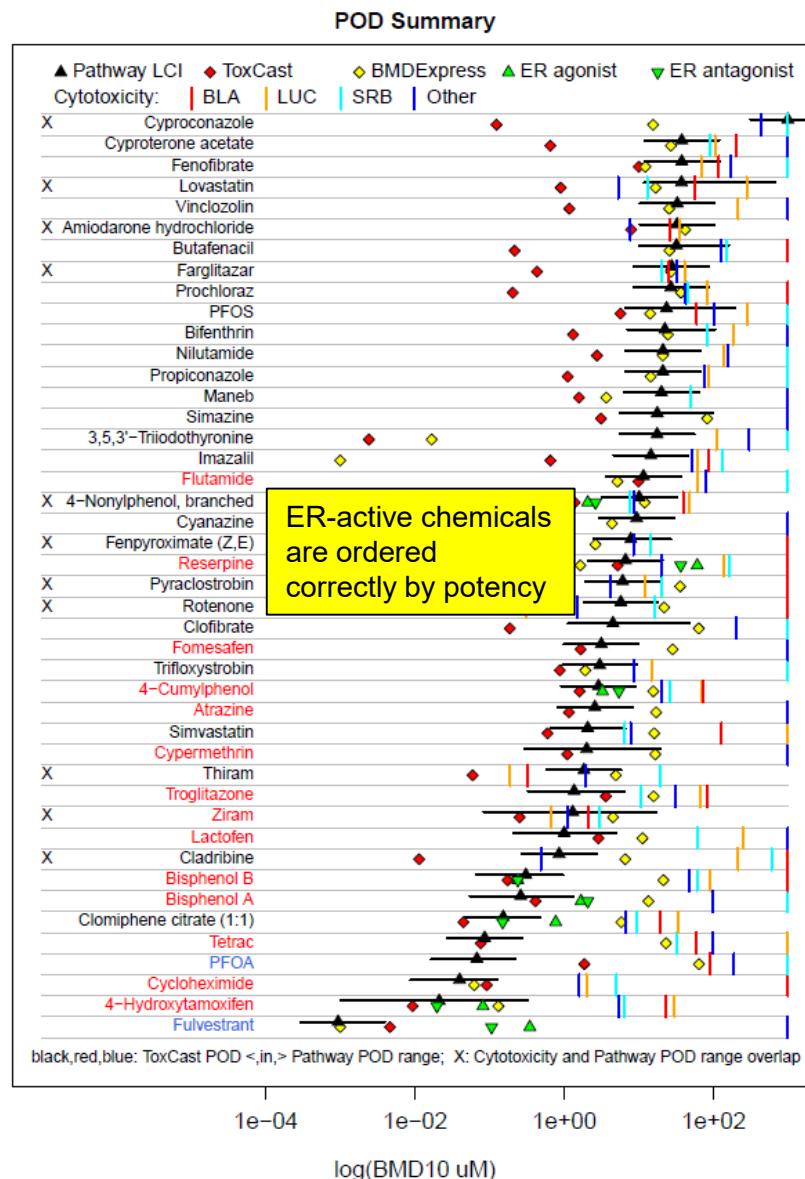

Steps to getting OECD acceptance

- IATA was reviewed and published in 2018-2019
 - Demonstrates an approach of interest
 - 1-2 years
- Defined Approach is to be reviewed in 2020
 - Gives more details of implementation
 - Will include proposal for specific assays that could be generally available and process for “validation” of these
 - 1-2 years
- Test Guideline(s) will likely be needed
 - These would give more specific details on how to run each assay and combine the results
 - Multiple years
- However, EPA and EFSA are already using the full ER model in making regulatory decisions

Other tools in the NAM Toolkit

High-throughput transcriptomics

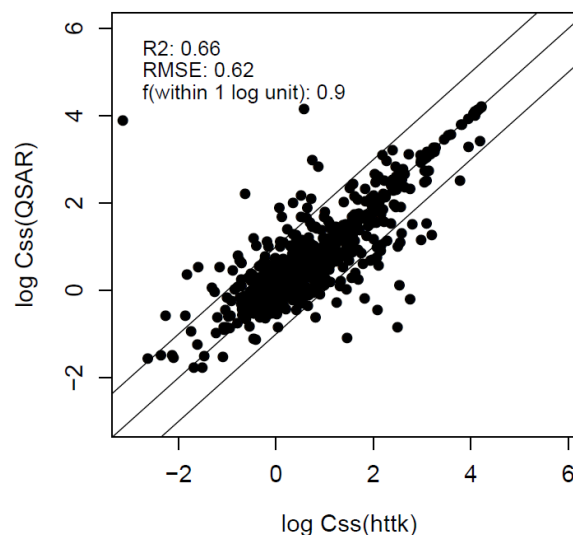

- Measures RNA (gene) changes in all ~20,000 genes at once
- Technology has been around for 10-20 years but cost has dramatically dropped in the last ~2 years without loss of quality
- Pilot results show that chemicals can simultaneously be screened for many mechanisms

Other tools in the NAM Toolkit

In vitro Toxicokinetics

- Generate cell-based measurements of plasma protein binding and intrinsic hepatic clearance
- Use a PBPK model to generate “C_{ss}”, concentration at steady-state give a 1 mg/kg/day oral dose
- $IVIVE\ POD = in\ vitro\ POD / C_{ss}$
- Compare IVIVE POD to exposure predictions to generate “Bioactivity to Exposure Ratio”, BER
- $BER \ll 1$ indicates low risk
- QSAR model can give adequate predictions of C_{ss}

Other tools in the NAM Toolkit

High-throughput exposure estimates

- Focus on Risk: compare hazard to exposure
- Build hierarchical models – exposure for some chemicals can be estimated more accurately than others
- SHEDS-HT – detailed use patterns drive exposure
- SEEM3 – more generic model
- Models are calibrated using measured exposure levels from NHANES

COMMENTS

Quantitative Risk Assessment Values

- ✓ IRIS values available
- ✗ No PPRTV values
- ✓ EPA RSL values available
- ✓ Minimum RfD: 0.050 mg/kg-day (chronic, IRIS, oral, 8)
- ✗ No RfC calculated
- ✗ IVIVE POD not calculated

Quantitative Hazard Values

- ✓ Minimum oral POD: 3.8 mg/kg-day (reproductive, HPVIS, oral, 6)
- ✗ No inhalation POD values
- ✓ Lowest Observed Bioactivity Equivalent Level: CYP1A1, CYP1A2

Cancer Information

- ✗ No cancer slope factor
- ✗ No inhalation unit risk value
- ✓ Carcinogenicity data available: University of Maryland carcinogeni
- ✗ No genotoxicity findings reported

Reproductive Toxicology

- ✓ Reproductive toxicity PODs available

Chronic Toxicology

- ✓ Chronic toxicity PODs available

Subchronic Toxicology

- ✓ Subchronic toxicity PODs available

Developmental Toxicology

- ✓ Developmental toxicity PODs available

Acute Toxicology

- ✓ Acute toxicity PODs available

Subacute Toxicology

- ✓ Subacute toxicity PODs available

Neurotoxicology

- ✗ No neurotoxicology data available

Endocrine System

- ✓ Endocrine Disruption Potential positive in 9 AR assays (tested)

ADME

- ✓ HTTK C_{ss} data are available

- EPA is developing databases and dashboards to make traditional and NAM data widely available and easy to use
- Comptox Chemicals Dashboard is the primary portal

EPA / OCSPP is developing a NAM Plan

1. Identification, Development and Integration of New Approach Methodologies (NAMs)
2. Establishing Scientific Relevance, Reliability and Confidence
3. Importance of Training, Education and Collaboration
4. Implementation of NAMs Under TSCA
 - Commitment of time and resources through the establishment of the TSCA NAM Team (TNT)
 - *“For the purposes of TSCA, EPA recognizes this new term (i.e., NAMs) as encompassing any ‘alternative test methods and strategies to reduce, refine, or replace vertebrate animals.’”*

https://www.epa.gov/sites/production/files/2018-06/documents/epa_alt_strat_plan_6-20-18_clean_final.pdf

Summary

- New approach methods (NAMs) are being developed to screen and prioritize chemicals using a combination of in silico and in vitro methods
- Regulatory acceptance requires demonstrating performance against various benchmarks
- Individual agencies (e.g. EPA and EFSA) are beginning to use NAMs, but wide acceptance requires OECD acceptance
 - IATA, DA, TG
