

(How) Should Risk Assessors Think with Models?

Matt Etterson

US EPA/ORD/CCTE

Great Lakes Toxicology and Ecology Division

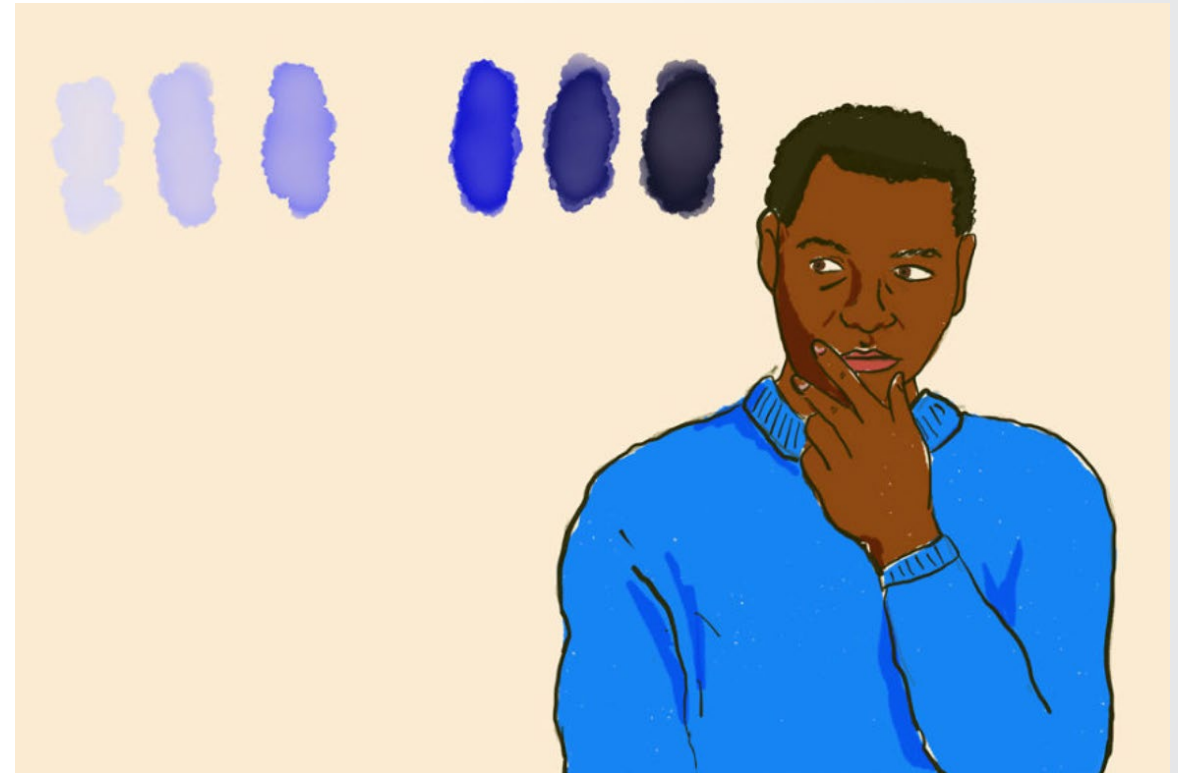

Duluth, MN, USA

? λ ,
 $Pr(\text{extinction})$

Presentation in 3 parts

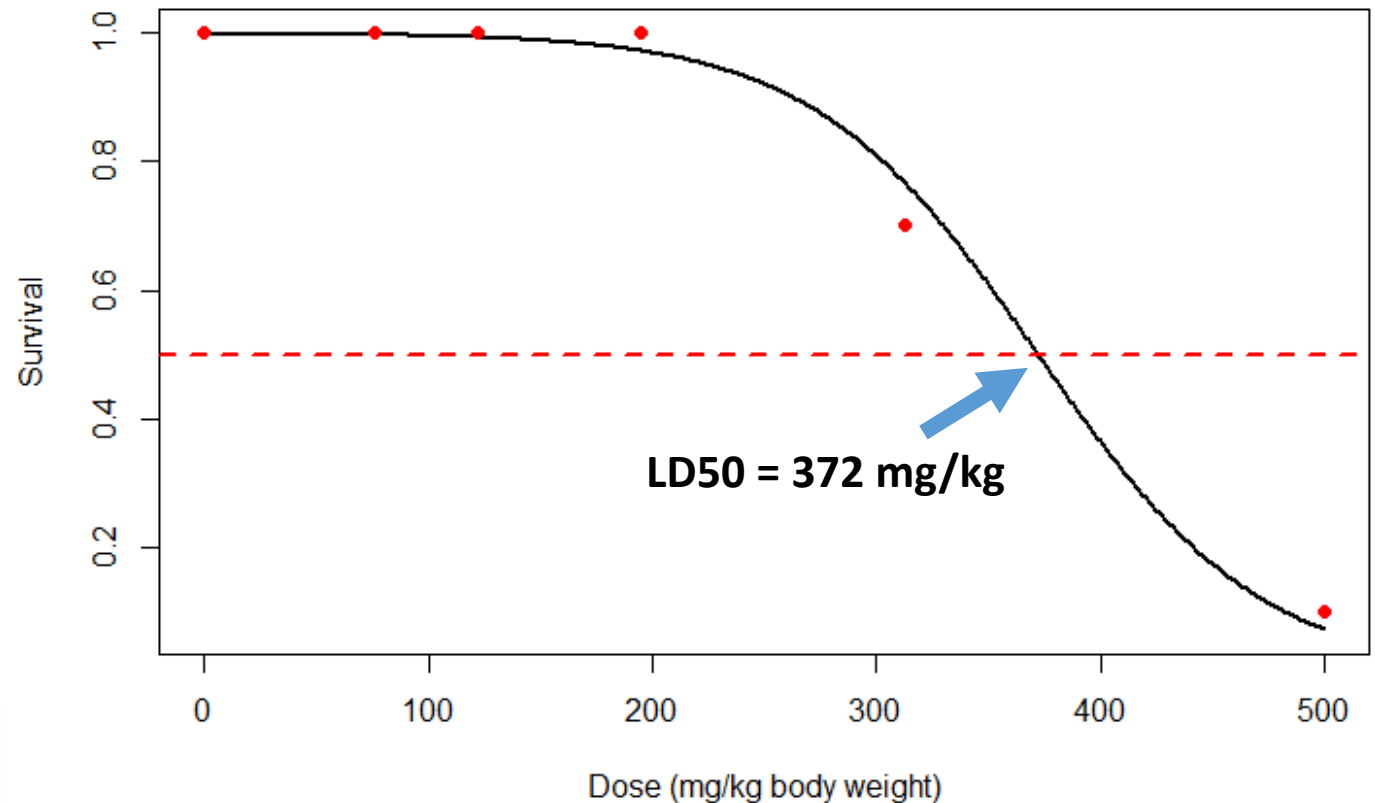

- Part I – Introduction to population modeling for risk assessment
- Part II – A couple of thought experiments
- Part III – (How) Should risk assessors think with models?

- EPA uses Risk Assessment to determine whether use is safe or not
 - For people, risk endpoints are individual measures of health/biological impairment
 - For other species, legislation targets protection of ***populations and/or communities***
- Mathematical models play a large role in Ecological Risk Assessment
 - Data analysis & inferential statistics
 - Extrapolation & forecasting

The dose-response experiment

- LD50 = the dose of a toxicant predicted to kill 50% of test subjects
- Fixed duration of observation (96-hours)
- 4-5 dose levels + control
- LD50 interpolated using regression techniques

Let's limber up our thought-experiment muscles

- 8,000 regulated pesticides (Federal Insecticide, Fungicide and Rodenticide Act)
- 80,000 non-pesticide chemicals (Toxic Substances Control Act)
- 700 bird species

Test	LD50
Duration	4 days
Total Time	675,000 years

**Conclusion – we
cannot test all
species for all
chemicals!**

Let's test all the species!
(Nate Pollesch)

We must extrapolate:

- From chemical A to chemical B
- From species A to species B
- From laboratory to field
- From individual to population

“We need models, lots of models”

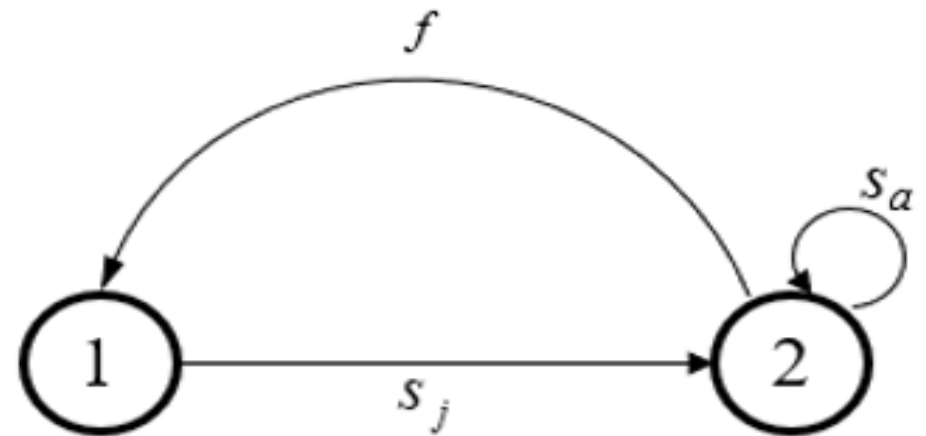

So, what is a population model?

- Dynamic model of the number of individuals in a population over time
- Typically incorporates vital rates (survival, growth, reproduction)
- Predictions include population growth rate, extinction probability, recovery time, equilibrium states

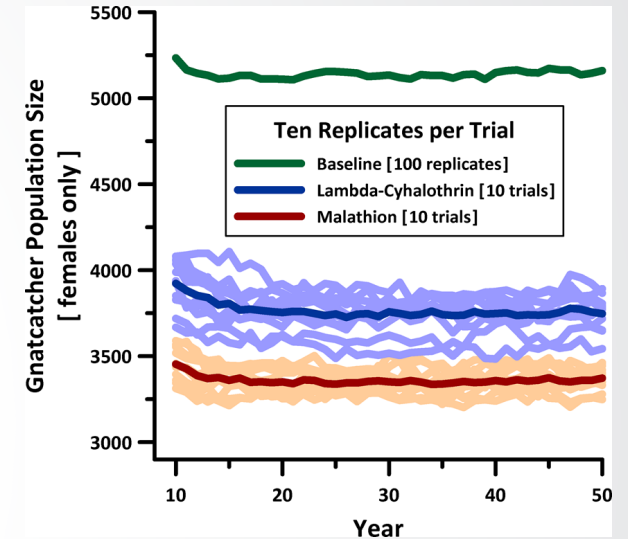

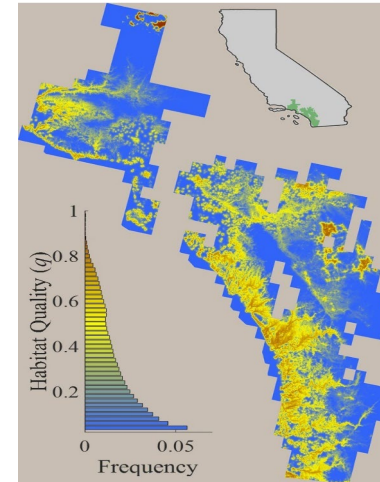

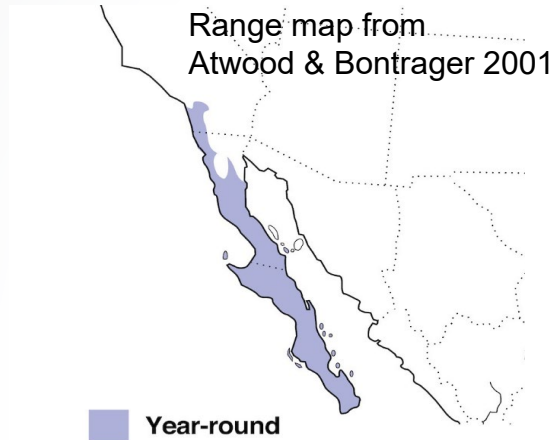

Parameters:

- S_a = annual adult survival
- S_j = annual juvenile survival
- β = annual reproductive success
- λ = annual rate of population change

$$\lambda = \frac{N_{t+1}}{N_t} = s_a + s_j\beta$$

How about an example?

- California Gnatcatcher
- Federally Threatened
- Habitat loss & nest parasitism
- Effect of pesticides unknown

- Mostly in Baja

- Pre-existing habitat map
- Spatially explicit simulation
- Spatially referenced pesticide use

- Pre-existing habitat map
- Spatially explicit simulation
- 50 year projections

Easy, right? So why are risk assessors skeptical?

Part II: A thought experiment to introduce thought experiments

- Suppose we build a population model that incorporates chemical effects (never mind the details)
- Further, suppose our model predicts $\lambda = N_{t+1}/N_t = 1.01 \pm 0.05$ (SE)
- What would happen to a population of 10,000 birds in 50 years?
- Answer 1: expected population size is 16,446 birds
- Answer 2: With 95% confidence, there will be between 100 birds and 1.7 million birds!
- Even with SE = 0.02, the 95% CI is 2,272 to 110,386 birds

1. Do birds live forever? (Miller & Botkin)

Assumption:

Adult birds do not senesce

- Let A = age
- N = population size
- Then: $Pr(A) = S^A$

- Solve for the expected age of the oldest bird ($Pr(A) = 1/N$): $A = -\frac{\ln(N)}{\ln(S)}$

- Royal Albatross suffer 3% mortality per year

Population Size	Expected age of oldest bird
$N = 1,000$	$A = 226$ yr
$N = 10,000$	$A = 302$ yr
$N = 100,000$	$A = 378$ yr

Conclusion: assumption that royal albatross do not senesce is false!

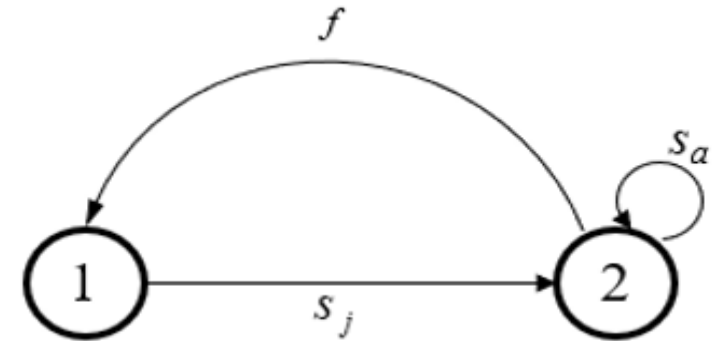

2. Is space just noise? (Pulliam)

Assumption:

Birds compete for limited high-quality breeding sites

Parameters:

- s_a = annual adult survival
- s_j = annual juvenile survival
- f = annual reproductive success
- λ = annual rate of population change

$$\lambda = \frac{N_{t+1}}{N_t} = s_a + s_j f$$

$$M = \begin{bmatrix} f s_j & f s_j \\ s_a & s_a \end{bmatrix}$$

2. Is space just noise? (Pulliam)

- Definition of source: $\lambda > 1$: ($N_{t+1} > N_t$).
- Assume \hat{n} available breeding sites in source
- What happens when all \hat{n} sites are occupied?
- Reproductive success for the population will be:
$$f(N) = \begin{cases} f & \text{if } N \leq \hat{n} \\ \frac{\hat{n}}{N} f & \text{if } N > \hat{n} \end{cases}$$
- Therefore, when all sites are occupied population growth rate is given by:
$$\lambda(N) = s_a + \frac{\hat{n}}{N} s_j f$$

2. Is space just noise? (Pulliam)

At equilibrium ($N^*: N_{t+1} = N_t$), $\lambda(N) = 1$

$$1 = s_a + \frac{\hat{n}}{N^*} s_j f$$

Subtract s_a :

$$1 - s_a = + \frac{\hat{n}}{N^*} s_j f$$

Multiply by N^* :

$$N^*(1 - s_a) = \hat{n} s_j f$$

Divide by $(1 - s_a)$:

$$N^* = \hat{n} \frac{s_j f}{(1 - s_a)}$$

But!:

$$s_a + s_j f > 1$$

$$s_j f > 1 - s_a$$

$$\frac{s_j f}{1 - s_a} > 1$$

Therefore:

$$N^* > \hat{n}$$

2. Is space just noise? (Pulliam)

- Definition of sink: $\lambda < 1$
- Assume only difference between source (habitat 1) and sink (habitat 2) is reproductive success ($f_1 \gg f_2$)
- Therefore:
 - Source: $\lambda_1 = s_a + s_j f_1 > 1$
 - Sink: $\lambda_2 = s_a + s_j f_2 < 1$

Pulliam showed that equilibrium ratio of source to sink (n_2/n_1) is estimated as:

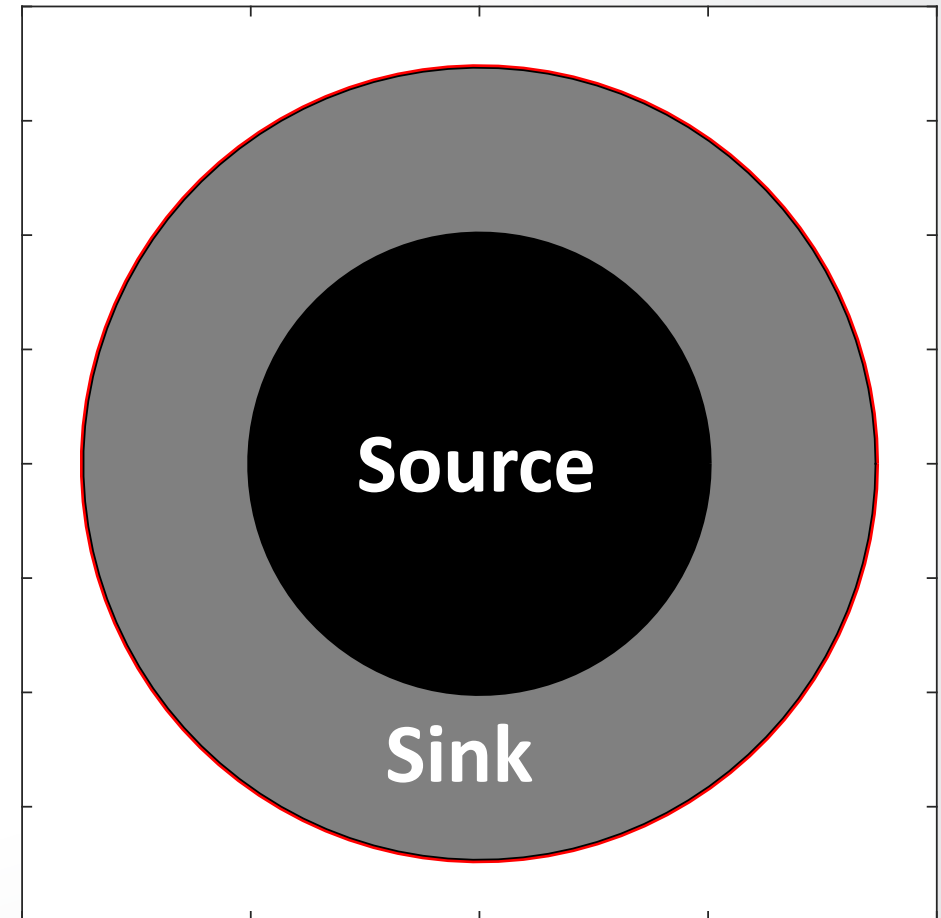

$$\frac{n_2}{n_1} = \frac{(\lambda_1 - 1)}{(1 - \lambda_2)}$$

2. Is space just noise? (Pulliam)

- $\lambda_1 = 1.1$, $\lambda_2 = 0.95$
- Sink population is 3 times the source population!

Conclusion(s):

- occupancy may be a misleading indicator of habitat quality
- Spatial habitat configuration may determine population growth rates
- Anthropogenic activities may create sinks

How did we learn from the examples?

1. Do birds live forever?

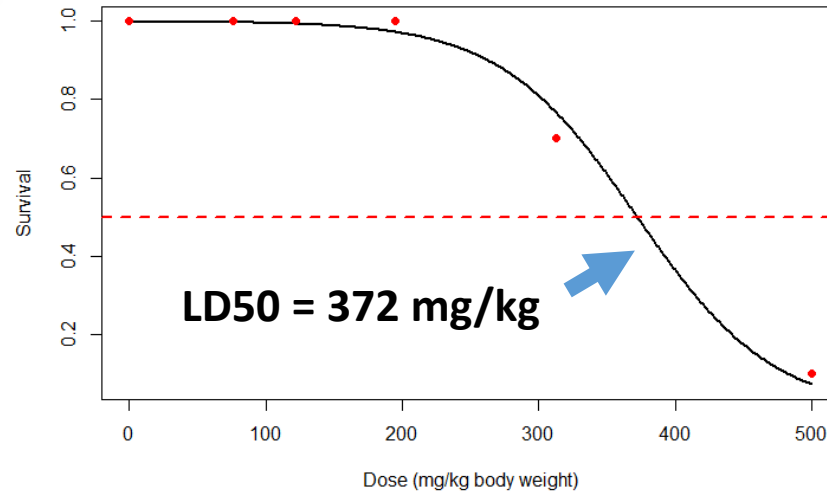

Used a *reductio* argument to reject an ***assumption***

2. Is space just noise?

Used a model to explore the emergent consequences of an ***assumption***

Thought experiments explore the consequences of assumptions

- Too many chemicals
- Too many species
- Not enough toxicity data
- Not enough time
- Models are too uncertain for forecasting

? λ ,
 $\longrightarrow Pr(\text{extinction})$

What do Risk Assessors want from pop models?

- To integrate separate toxicological effects on survival, growth, and reproduction into a single metric of effect (λ)
- To identify sensitive life-history stages
- To incorporate adverse outcome pathways
- To study the interaction between environment and chemical stressors

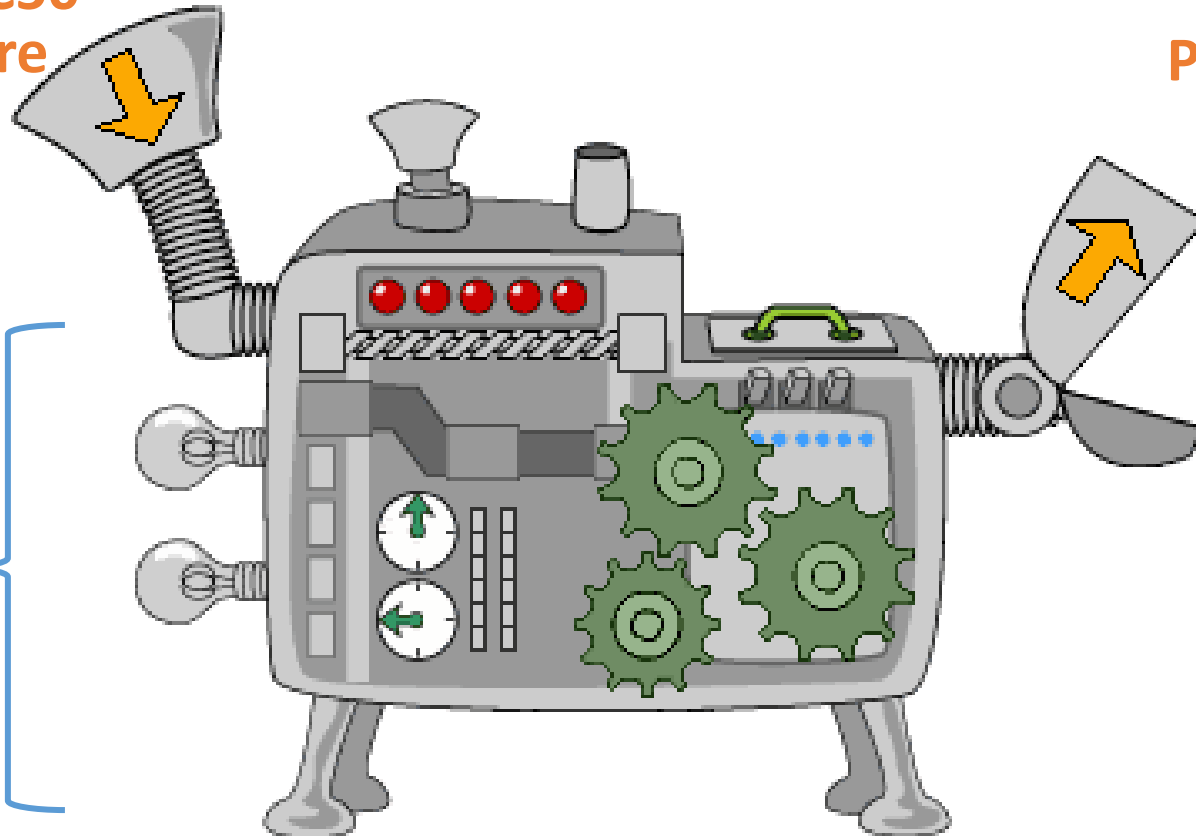

Toward a foundation for ecotoxicological thought experiments

Endogenous systems

Lifecycle

Landscape maps

OK, maybe...let's see some examples

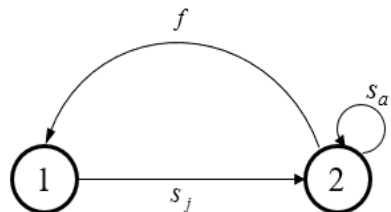

Parameter definitions:

- s_j = survival from fledging to 1st year
- s_a = survival after 1st year
- f = annual fecundity (offspring/year)
- p = breeding propensity

Lifecycle from Young 1968. Ecology

The lifecycle graph and model are isoinformatic

Tree Swallow

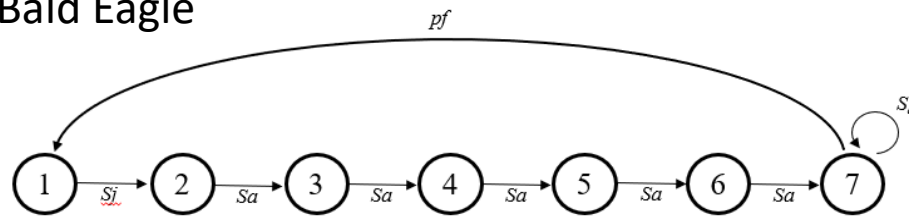

Lifecycle adapted from Pulliam 1988. American Naturalist

$$M = \begin{bmatrix} f s_j & f s_j \\ s_a & s_a \end{bmatrix}$$

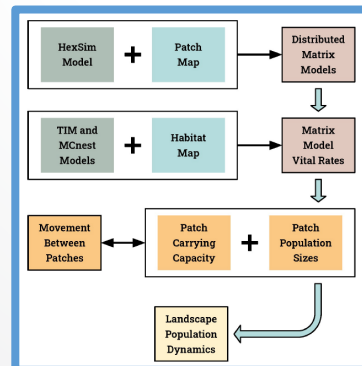

Bald Eagle

Lifecycle from Young 1968. Ecology

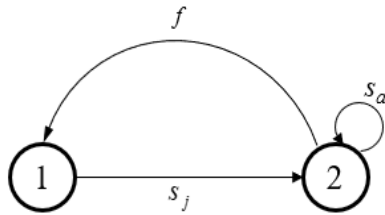

$$M = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 & pf \\ s_j & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & s_a & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & s_a & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & s_a & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & s_a & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & s_a & s_a \end{bmatrix}$$

Stakeholders can reach consensus on the lifecycle graph without reference to the mathematics

Fitness predictions

Tree Swallow

$$M = \begin{bmatrix} f s_j & f s_j \\ s_a & s_a \end{bmatrix}$$

Fitness predictions:

- Intrinsic fitness (λ_f) = expected annual production of genetic descendants (including self)
- Lifetime reproductive success (LRS) = expected lifetime production of offspring

$$\lambda_f = s_a + f s_j$$

$$LRS = f \frac{s_j}{1 - s_a}$$

What do Risk Assessors want from pop models?

- ✓ To integrate separate toxicological effects on survival, growth, and reproduction into a single metric of effect (λ)
- To identify sensitive life-history stages
- To incorporate adverse outcome pathways
- To study the interaction between environment and chemical stressors

Identification of sensitive life stages

		$\lambda_f = s_a + fs_j$	$LRS = f \frac{s_j}{1 - s_a}$
Process	Parameter	λ_f Sensitivity	LRS Sensitivity
Juvenile Survival	s_j	$\frac{\partial \lambda_f}{\partial s_j} = f$	$\frac{\partial LRS}{\partial s_j} = \frac{f}{1 - s_a}$
Adult Survival	s_a	$\frac{\partial \lambda_f}{\partial s_a} = 1$	$\frac{\partial LRS}{\partial s_a} = \frac{s_j f}{(1 - s_a)^2}$
Fecundity	f	$\frac{\partial \lambda_f}{\partial f} = s_j$	$\frac{\partial LRS}{\partial f} = \frac{s_j}{(1 - s_a)}$

***A priori* ordering of sensitivities:**

- Juvenile survival (s_j) is the most sensitive process
- Practical utility – a formal way of weighting the results of toxicity tests

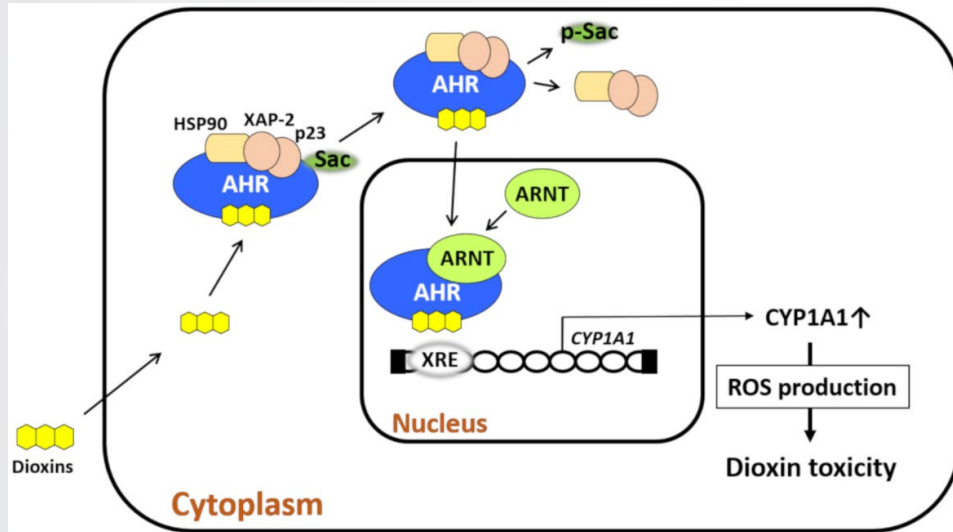

$$f > 1 > s_j$$

What do Risk Assessors want from pop models?

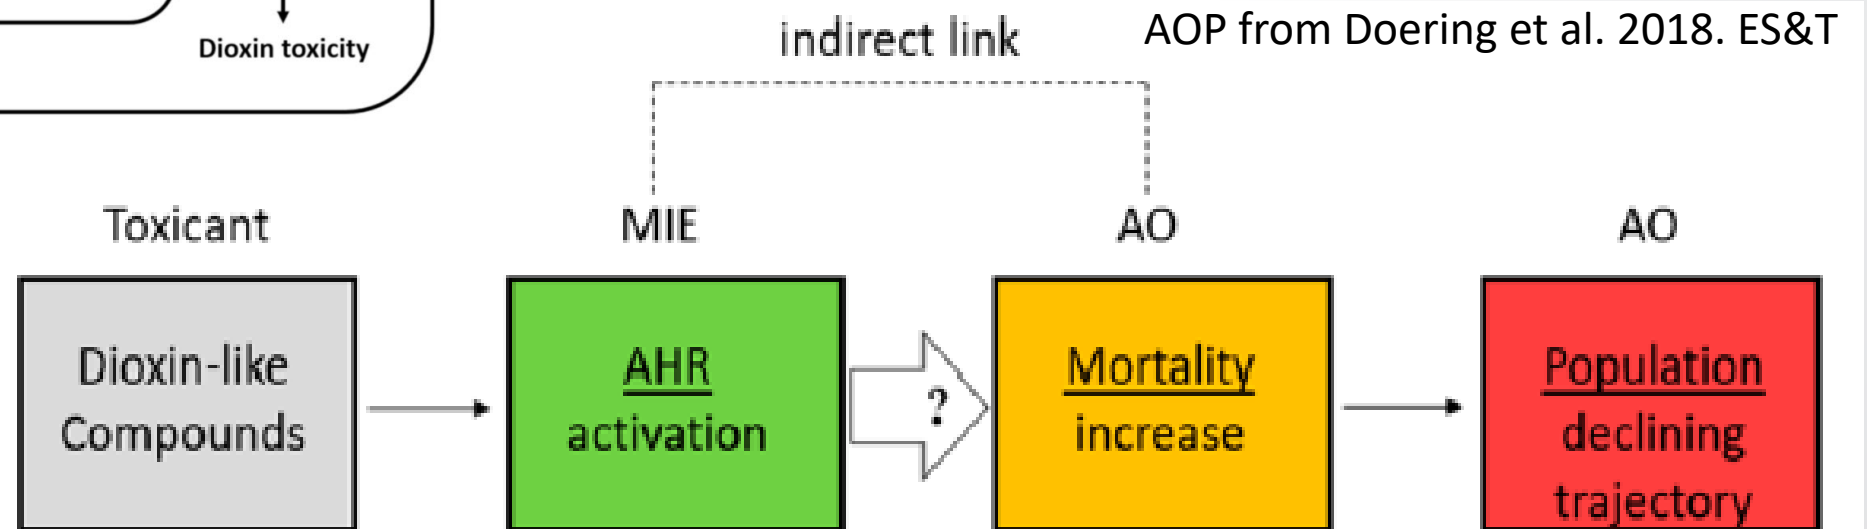

- ✓ To integrate separate toxicological effects on survival, growth, and reproduction into a single metric of effect (λ)
- ✓ To identify sensitive life-history stages
- To incorporate adverse outcome pathways
- To study the interaction between environment and chemical stressors

What do Risk Assessors want from pop models?

- ✓ To integrate separate toxicological effects on survival, growth, and reproduction into a single metric of effect (λ)
- ✓ To identify sensitive life-history stages
- ✓ To incorporate adverse outcome pathways
- To study the interaction between environment and chemical stressors

What do Risk Assessors want from pop models?

- ✓ To integrate separate toxicological effects on survival, growth, and reproduction into a single metric of effect (λ)
- ✓ To identify sensitive life-history stages
- ✓ To incorporate adverse outcome pathways
- ∅ To study the interaction between environment and chemical stressors

ELMs are a great foundation for exploring the consequences of assumptions about toxicity

The ELM Advantage:

- (relatively) easy to formulate
- Rapid analysis
- Ideal for questions about the consequences of upstream events
